University of the Witwatersrand, Johannesburg  
Software Development II

## Class Test 2023: 1 Hour 30 Minutes – 35 marks

### Instructions

- Answer *all* questions. The questions do not carry equal weight.
- For questions which require you to write source code, note that:
  - You only need to specify `#include's` if specifically asked.
  - For classes, you can give the implementation entirely in the header file, unless directed otherwise.
  - Marks are not awarded solely for functionality but also for good design, making appropriate use of library functions, following good coding practices, and using a modern, idiomatic C++ style.
  - Your code must be easily understandable or well commented.
  - You may use pencil but then you forfeit the right to query the marks.
- Reference sheets are provided.

### Question 1

A *palindrome* is a word, phrase or sentence that reads the same backwards or forwards, for example, the word “nun” is a palindrome. Two famous examples of longer palindromes are:

“Madam, in Eden, I’m Adam.”

“A man, a plan, a canal - Panama!”

Write either a standalone function, or a class which contains a public member function, that identifies whether a given string is a palindrome. The function’s signature must be as follows:

```
bool isPalindrome(const string& text);
```

You need to ignore both letter case and punctuation when determining if text is a palindrome. In other words, `true` will be returned for the above examples. If text contains no letters, then `false` should be returned.

Higher marks will be awarded for solutions which avoid the use of looping structures.

Hint: Remember that a `string` is a vector of characters, and vector’s member functions can be used on strings. Also, STL algorithms can be used with iterators provided by strings.

[Total Marks 12]

## Question 2

A magic square is an arrangement of numbers from 1 to  $n^2$  in an  $[n \times n]$  matrix, with each number occurring exactly once, and such that the sum of the entries of any row, any column, or any main diagonal is the same.

One method of generating a magic square in cases where  $n$  is odd is as follows: Place a 1 in any location (in the centre position of the top row, for example), then place each subsequent number in the square one unit above and to the right. The counting is wrapped around, so that falling off the top returns on the bottom and falling off the right returns on the left. When a position is encountered which is already filled, the next number is instead placed below the previous one and the method continues as before.

The code in Listing 1 produces a magic square using this method and the output is given in Listing 2.

```
1  typedef vector<vector<int>> Matrix;
2
3  int main()
4  {
5      int k, g, unit;
6      int row, col, newRow, newCol;
7      int n = 5;
8      Matrix square{{0, 0, 0, 0, 0},
9                    {0, 0, 0, 0, 0},
10                   {0, 0, 0, 0, 0},
11                   {0, 0, 0, 0, 0},
12                   {0, 0, 0, 0, 0}};
13
14     unit = 1;
15     row = 1;
16     col = (n + 1) / 2;
17     k = 1;
18     square[row - 1][col - 1] = k;
19
20     for (k = 2; k <= n * n; k++)
21     {
22         newRow = row - 1;
23         newCol = col + 1;
24         if (newRow == 0 && newCol == (n + 1))
25         {
26             newRow = row + 1;
27             newCol = n;
28             row = newRow;
29             col = newCol;
30             square[row - 1][col - 1] = k;
31         }
32         else
33         {
34             if (newRow == 0)
35             {
36                 newRow = n;
37             }
38             if (newCol == (n + 1))
39             {
40                 newCol = 1;
41             }
42         }
43     }
44 }
```

```

42         if (square[newRow - 1][newCol - 1] == 0)
43         {
44             row = newRow;
45             col = newCol;
46             square[row - 1][col - 1] = k;
47         }
48         else
49         {
50             newRow = row + 1;
51             newCol = col;
52             if (newRow == (n + 1))
53             {
54                 newRow = 1;
55             }
56             row = newRow;
57             col = newCol;
58             square[row - 1][col - 1] = k;
59         }
60     }
61 }
62
63 for (int i = 0; i < n; i++)
64 {
65     for (int j = 0; j < n; j++)
66     { // format output nicely
67         cout << setiosflags(ios::left) << setw(5) <<
68             square[i][j];
69     }
70     cout << endl;
71 }
72 return 0;
73 }

```

**Listing 1:** Code for generating a  $5 \times 5$  magic square

17	24	1	8	15
23	5	7	14	16
4	6	13	20	22
10	12	19	21	3
11	18	25	2	9

**Listing 2:** Console output for the magic square generator

Your task is to refactor the given code in order to improve its structure and make it easier to understand. You should make use of functions and apply good coding principles and practices. Note that the refactored code must produce identical output, and you must continue to use `Matrix`.

[Total Marks 15]

### Question 3

- a) Describe two situations when comments should accompany code. (4 marks)
- b) What kinds of software artefacts should not be under version control? Give an explanation as to why this should be the case. (4 marks)

[Total Marks 8]

## <vector> class

---

Assume that `T` is some type (eg, `int`). Assume the following declarations:

```
T e;
vector<T> v, v1;
vector<T>::iterator iter, iter2, beg, end;
(use vector<T>::const_iterator or vector<T>::reverse_iterator if appropriate)
int i, n, size;
bool b
```

### Methods and operators

#### Constructors and destructors

<code>vector&lt;T&gt; v;</code>	Creates an empty vector of T's.
<code>vector&lt;T&gt; v(n);</code>	Creates vector of n default values.
<code>vector&lt;T&gt; v(n, e);</code>	Creates vector of n copies of e.
<code>vector&lt;T&gt; v(beg, end);</code>	Creates vector with elements copied from range beg..end.
<code>v.~vector&lt;T&gt;();</code>	Destroys all elems and frees memory.

#### Size

<code>i = v.size();</code>	Number of elements.
<code>i = v.capacity();</code>	Max number of elements before reallocation.
<code>i = v.max_size();</code>	Implementation max number of elements.
<code>b = v.empty();</code>	True if empty. Same as <code>v.size()==0</code>
<code>v.reserve(size);</code>	Increases capacity to <code>size</code> before reallocation

#### Altering

<code>v = v1;</code>	Assigns <code>v1</code> to <code>v</code> .
<code>v[i] = e;</code>	Sets <code>i</code> th element. Subscripts from zero.
<code>v.at(i) = e;</code>	As subscription, but may throw <code>out_of_range</code> .
<code>v.push_back(e);</code>	Adds <code>e</code> to end of <code>v</code> . Expands <code>v</code> if necessary.
<code>v.pop_back();</code>	Removes last element of <code>v</code> .
<code>v.clear();</code>	Removes all elements.
<code>v.assign(n, e);</code>	Replaces existing elements with n copies of <code>e</code> .
<code>v.assign(beg, end);</code>	Replaces existing elements with copies from range beg..end.
<code>iter2 = v.insert(iter, e);</code>	Inserts a copy of <code>e</code> at <code>iter</code> position and returns its position.
<code>v.insert(iter, n, e);</code>	Inserts n copies of <code>e</code> starting at <code>iter</code> position.
<code>v.insert(iter, beg, end);</code>	Inserts all elements in range beg..end, starting at <code>iter</code> position.
<code>iter2 = v.erase(iter);</code>	Removes element at <code>iter</code> position and returns position of next element.
<code>iter2 = v.erase(beg, end);</code>	Removes range beg..end and returns position of next element.

#### Access

<code>e = v[i];</code>	<code>i</code> th element. No range checking.
<code>e = v.at(i);</code>	As subscription, but may throw <code>out_of_range</code> .
<code>e = v.front();</code>	First element. No range checking.
<code>e = v.back();</code>	Last element. No range checking.

#### Iterators

<code>beg = v.begin();</code>	Returns iterator to first element.
<code>end = v.end();</code>	Returns iterator to <i>after</i> last element.
<code>beg = v.rbegin();</code>	Returns reverse iterator to first (in reverse order) element.

```
end = v.rend();
```

Returns reverse iterator to *after* last (in reverse order) element.

---

## <string> class

---

Assume the following declarations:

```
string s, s1, s2;  
char c; char* cs;  
string::size_type i, start, len, start1, len1, start2, len2, pos, newSize;
```

---

### Methods and operators

---

#### Constructors and destructors

```
string s;  
string s(s1);  
string s(cs);
```

Creates a string variable.  
Creates s; initial value from s1.  
Creates s; initial value from cs.

#### Altering

```
s1 = s2;  
s1 = cs;  
s1 = c;  
s[i] = c;  
s.at(i) = c;  
  
s.append(s2);  
s.append(cs);  
s.assign(s2, start, len);  
s.clear();  
s.insert(start, s1);  
s.erase(start, len);
```

Assigns s2 to s1.  
Assigns C-string cs to s1.  
Assigns char c to s1.  
Sets ith character. Subscripts from zero.  
As subscription, but throws `out_of_range` if *i* isn't in string.  
Concatenates s2 on end of s. Same as `s += s2`;  
Concatenates cs on end of s. Same as `s += cs`;  
Assigns s2[start..start+len-1] to s.  
Removes all characters from s  
Inserts s1 into s starting at position *start*.  
Deletes a substring from s. The substring starts at position *start* and is *len* characters in length.

#### Access

```
cs = s.c_str();  
s1 = s.substr(start, len);  
c = s[i];  
c = s.at(i);
```

Returns the equivalent c-string.  
s[start..start+len-1].  
ith character. Subscripts start at zero.  
As subscription, but throws `out_of_range` if *i* isn't in string.

#### Size

```
i = s.length();  
i = s.size();  
i = s.capacity();  
  
b = s.empty();  
i = s.resize(newSize, padChar);
```

Returns the length of the string.  
Same as `s.length()`  
Number of characters s can contain without reallocation.  
True if empty, else false.  
Changes size to *newSize*, padding with *padChar* if necessary.

#### Searching

All searches return `string::npos` on failure. The *pos* argument specifies the starting position for the search, which proceeds towards the end of the string (for "first" searches) or towards the beginning of the string (for "last" searches); if *pos* is not specified then the whole string is searched by default.

```
i = s.find(c, pos);  
i = s.find(s1, pos);  
i = s.rfind(s1, pos);  
i = s.find_first_of(s1, pos);  
  
i = s.find_first_not_of(s1, pos);  
i = s.find_last_of(s1, pos);  
i = s.find_last_not_of(s1, pos);
```

Position of leftmost occurrence of char *c*.  
Position of leftmost occurrence of *s1*.  
As find, but right to left.  
Position of first char in s which is in s1 set of chars.  
Position of first char of s not in s1 set of chars.  
Position of last char of s in s1 set of chars.  
Position of last char of s not in s1 set of chars.

## Comparison

```
i = s.compare(s1);  
i = s.compare(start1, len1, s1,  
start2, len2);
```

```
b = s1 == s2  
also > < >= <= !=
```

## Input / Output

```
cin >> s;  
getline(cin, s);  
cout << s;
```

<0 if s<s1, 0 if s==s1, or >0 if s>s1.

Compares s[start1..start1+len1-1] to s1[start2..start2+len2-1]. Returns value as above.

The comparison operators work as expected.

>> overloaded for string input.

Next line (without newline) into s.

<< overloaded for string output.

---

## Concatenation

---

The + operator is overloaded to concatenate two strings.

```
| s = s1 + s2;
```

Similarly the += operator is overloaded to append strings.

```
| s += s2;  
| s += cs;  
| s += c;
```

---

## Reference Sheets

### 1 doctest Framework

```
TEST_CASE("This is a test case")
{
    CHECK(expression);           // assertion passes if expression is true
    CHECK_FALSE(expression);     // assertion passes if expression is false
    CHECK_THROWS(expression);    // assertion passes if an exception of any
                                // type is thrown by expression
    CHECK_NOTHROW(expression);   // assertion passes if no exception is thrown
                                // by expression
    CHECK_THROWS_AS(expression, exception_type); // assertion passes if
                                // expression throws an exception of exception_type
    CHECK(doctest::Approx(left) == right); // assertion passes if left is
                                // approximately equal to right (floating point comparison)
}
```

**Listing 1:** doctest framework: syntax and assertions

### 2 Algorithms

The following tables provide information on some of the algorithms which are available in `<algorithm>`. Arguments which are repeatedly used in the function signatures are explained below. All of this information has been adapted from: <http://www.cplusplus.com/reference/algorithm/>.

Function Arguments	
first and last	Represent a pair of iterators which specify a range. The range specified is <code>[first,last)</code> , which contains all the elements between first and last, including the element pointed to by first but not the element pointed to by last.
result	Represents an iterator pointing to the start of the output range.
val, old_value, new_value	Represent elements which are of the same type as those contained in the range.
pred	Represents a function which accepts an element in the range as its only argument. The function returns either true or false indicating whether the element fulfills the condition that is checked. The function shall not modify its argument. pred can either be a function pointer or a function object.

Non-Modifying Sequence Operations	
<code>all_of(first, last, pred)</code>	Returns true if <code>pred</code> returns true for all the elements in the specified range or if the range is empty, and false otherwise.
<code>any_of(first, last, pred)</code>	Returns true if <code>pred</code> returns true for any of the elements in the specified range, and false otherwise.
<code>none_of(first, last, pred)</code>	Returns true if <code>pred</code> returns false for all the elements in the specified range or if the range is empty, and false otherwise.
<code>for_each(first, last, fn)</code>	Applies function <code>fn</code> to each of the elements in the specified range. <code>fn</code> accepts an element in the range as its argument. Its return value, if any, is ignored. <code>fn</code> can either be a function pointer or a function object.
<code>find(first, last, val)</code>	Returns an iterator to the first element in the specified range that compares equal to <code>val</code> . If no such element is found, the function returns <code>last</code> . The function uses <code>operator==</code> to compare the individual elements to <code>val</code> .
<code>find_if(first, last, pred)</code>	Returns an iterator to the first element in the specified range for which <code>pred</code> returns true. If no such element is found, the function returns <code>last</code> .
<code>find_first_of(first1, last1, first2, last2)</code>	Returns an iterator to the first element in the range <code>[first1,last1)</code> that matches any of the elements in <code>[first2,last2)</code> . If no such element is found, the function returns <code>last1</code> . The elements in <code>[first1,last1)</code> are sequentially compared to each of the values in <code>[first2,last2)</code> using <code>operator==</code> .
<code>count(first, last, val)</code>	Returns the number of elements in the specified range that compare equal to <code>val</code> . The function uses <code>operator==</code> to compare the individual elements to <code>val</code> .
<code>equal(first1, last1, first2)</code>	Compares the elements in the range <code>[first1,last1)</code> with those in the range beginning at <code>first2</code> , and returns true if all of the elements in both ranges match, and false otherwise. The elements are compared using <code>operator==</code> .
<code>search_n(first, last, count, val)</code>	Searches the specified range for a sequence of successive <code>count</code> elements, each comparing equal to <code>val</code> . The function returns an iterator to the first of such elements, or <code>last</code> if no such sequence is found.
<code>binary_search(first, last, val)</code>	Returns true if any element in the specified range is equivalent to <code>val</code> , and false otherwise. The elements are compared using <code>operator&lt;</code> . Two elements, <code>a</code> and <code>b</code> are considered equivalent if <code>(!(a&lt;b) &amp;&amp; !(b&lt;a))</code> . The elements in the range <i>shall already be sorted</i> according to this same criterion ( <code>operator&lt;</code> ). The function optimizes the number of comparisons performed by comparing non-consecutive elements of the sorted range, which is especially efficient for random-access iterators.
<code>min_element(first, last)</code>	Returns an iterator pointing to the element with the smallest value in the specified range. The comparisons are performed using <code>operator&lt;</code> . An element is the smallest if no other element compares less than it. If more than one element fulfills this condition, the iterator returned points to the first of such elements.
<code>max_element(first, last)</code>	Returns an iterator pointing to the element with the largest value in the specified range. The comparisons are performed using <code>operator&lt;</code> . An element is the largest if no other element does not compare less than it. If more than one element fulfills this condition, the iterator returned points to the first of such elements.

Modifying Sequence Operations	
<code>copy(first, last, result)</code>	Copies the elements in the range <code>[first,last)</code> into the range beginning at <code>result</code> . The function returns an iterator to the end of the destination range (which points to the element following the last element copied). The ranges shall not overlap in such a way that <code>result</code> points to an element in the range <code>[first,last)</code> .
<code>transform(first, last, result, op)</code>	Applies the function <code>op</code> to each of the elements in the specified range and stores the value returned by <code>op</code> in the range that begins at <code>result</code> . <code>op</code> can either be a function pointer or a function object. The <code>transform</code> function allows for the destination range to be the same as the input range to make transformations <i>in place</i> . <code>transform</code> returns an iterator pointing to the element that follows the last element written in the <code>result</code> sequence.
<code>replace(first, last, old_value, new_value)</code>	Assigns <code>new_value</code> to all the elements in the specified range that compare equal to <code>old_value</code> . The function uses <code>operator==</code> to compare the individual elements to <code>old_value</code> . No value is returned.
<code>replace_if(first, last, pred, new_value)</code>	Assigns <code>new_value</code> to all the elements in the specified range for which <code>pred</code> returns <code>true</code> . No value is returned.
<code>fill(first, last, val)</code>	Assigns <code>val</code> to all the elements in the specified range. No value is returned.
<code>remove(first, last, val)</code>	Transforms the specified range into a range with all the elements that compare equal to <code>val</code> removed, and returns an iterator to the new end of that range. The function does not alter the size of the container containing the range of elements. The removal is done by replacing the elements that compare equal to <code>val</code> by the next element that does not, and signalling the new size of the shortened range by returning an iterator to the element that should be considered its new past-the-end element. The relative order of the elements not removed is preserved, while the elements between the returned iterator and <code>last</code> are left in a valid but unspecified state. The function uses <code>operator==</code> to compare the individual elements to <code>val</code> .
<code>remove_if(first, last, pred)</code>	Transforms the specified range into a range with all the elements for which <code>pred</code> returns <code>true</code> removed, and returns an iterator to the new end of that range. The function does not alter the size of the container containing the range of elements. The removal is done by replacing the elements for which <code>pred</code> returns <code>true</code> by the next element that does not, and signalling the new size of the shortened range by returning an iterator to the element that should be considered its new past-the-end element. The relative order of the elements not removed is preserved, while the elements between the returned iterator and <code>last</code> are left in a valid but unspecified state.
<code>unique(first, last)</code>	Removes all but the first element from every consecutive group of equivalent elements in the specified range. The function does not alter the size of the container containing the range of elements. The removal is done by replacing the duplicate elements by the next element that is not a duplicate, and signalling the new size of the shortened range by returning an iterator to the element that should be considered its new past-the-end element. The relative order of the elements not removed is preserved, while the elements between the returned iterator and <code>last</code> are left in a valid but unspecified state. The function uses <code>operator==</code> to compare the pairs of elements.

Modifying Sequence Operations	
<code>reverse(first, last)</code>	Reverses the order of the elements in the specified range. There is no return value.
<code>sort(first, last)</code>	Sorts the elements in the specified range into ascending order. The elements are compared using operator <code>&lt;</code> . There is no return value.

## <locale> Members

The <locale> header file includes functions for character classification. These are listed below.

<code>bool isalnum(char c)</code>	Returns true if the character tested is alphanumeric; false if it is not.
<code>bool isalpha(char c)</code>	Returns true if the character tested is alphabetic; false if it is not.
<code>bool iscntrl(char c)</code>	Returns true if the character tested is a control character; false if it is not.
<code>bool isdigit(char c)</code>	Returns true if the character tested is a numeric; false if it is not.
<code>bool isgraph(char c)</code>	Returns true if the character tested is alphanumeric or a punctuation character; false if it is not.
<code>bool isupper(char c)</code>	Returns true if the character tested is uppercase; false if it is not.
<code>bool islower(char c)</code>	Returns true if the character tested is lowercase; false if it is not.
<code>bool isprint(char c)</code>	Returns true if the character tested is a printable; false if it is not.
<code>bool ispunct(char c)</code>	Returns true if the character tested is a punctuation character; false if it is not.
<code>bool isspace(char c)</code>	Returns true if the character tested is a whitespace; false if it is not.
<code>bool isxdigit(char c)</code>	Returns true if the character tested is a character used to represent a hexadecimal number; false if it is not.
<code>char tolower(char c)</code>	Returns the character converted to lower case.
<code>char toupper(char c)</code>	Returns the character converted to upper case.
